Multiplication

How do I multiply two numbers without a calculator?

- There are a variety of written methods that can be used to add large numbers
  - You only need to know **one** method, but be able to use it confidently
  - Four common methods are described below, but there are many other valid methods

How do I use the column method?

- This is an efficient method if you are confident with multiplication
- To use the **column method**:
  - Write one number above the other lining up the digits using **place value columns**
  - Multiply the first digit (on the right) from the bottom value by each digit in the top value
    - Write the result under the line with the digits in the correct place value columns
  - Multiply the next digit in the bottom value by each digit in the top value
    - Always work from **right to left**
    - Use 0s as place holders when multiplying digits in columns other than the ones column

Stuck on something?
Ask questions and get help with exactly what you're revising.
Got it

$$
\begin{array}{r}
522 \\
1740 \\
34800 \\
\hline
37062
\end{array}
$$

How do I use the lattice method?

- The lattice method is good for numbers with two or more digits
  - This method allows you to work with individual digits
- To use the **lattice method**:
  - Draw a grid
    - The **number of rows** should be the same as the number of digits in one number
    - The **number of columns** should be the same as the number of digits in the other number
    - Draw diagonal lines through the boxes
  - Multiply each pair of digits, writing the result in the relevant box
    - Ones should be written in the bottom half of the box and tens in the top half of the box
  - Add the digits along the diagonals and write the result in the diagonal outside the grid
    - Carry the tens of any 2 digit result into the next diagonal
- For example, 2879 × 36 = 103 644

How do I use the grid method?

- This method keeps the value of the larger number intact
  - It may take longer with two larger numbers
  - Be careful lining up numbers with lots of zeros!
- To use the **grid method**
  - Draw a grid
    - The **number of rows** should be the same as the number of digits in one number
    - The **number of columns** should be the same as the number of digits in the other number
  - Label the rows and columns with the values of each digit
    - E.g. For 3516 you would use 3000, 500, 10 and 6
  - Multiply together the relevant values and put the results in the boxes

	3000	500	10	6
7	21 000	3500	70	42

How do I use the repeated addition method?

- This is best for smaller, simpler cases
  - You may have seen this called 'chunking'
- To use the **repeated addition method**
  - Build up to the answer using simple multiplication facts that can be worked out easily
  - To find 13×23 :
    $1 \times 23 = 23$
    $2 \times 23 = 46$
    $4 \times 23 = 92$
    $8 \times 23 = 184$
  - So, $13 \times 23 = 1 \times 23 + 4 \times 23 + 8 \times 23 = 23 + 92 + 184 = 299$

What words are used for multiplication and division?

- **Multiplication** may be phrased using the words **lots of, times** or **product**
- **Division** may be phrased using the words **quotient, share** and **per**

Examiner Tips and Tricks

A good way to check your answer without a calculator is to estimate it (e.g. by rounding everything to 1 significant figure).

Worked Example

Multiply 725 by 19.

Answer:

Using the grid method

- Split the numbers up using the place value
- Multiply numbers to fill in the grid

×	700	20	5
10	7000	200	50
9	6300	180	45

$$
\begin{array}{r}
50 \\
6300 \\
180 \\
+\quad 45 \\
\hline
13775
\end{array}
$$

Use an estimate to check your answer

- 700×20 is equal to 14 000

725 × 19 = 13 775

Division

How do I divide a number by another without a calculator?

- The most common written method for division is short division (or "the bus stop method")
  - There are other methods such as long division, but short division is generally the most efficient
- While short division is best when dividing by a single digit, for bigger numbers you may need a different approach
- You can use other number skills to help
  - eg. cancelling fractions, “shortcuts” for dividing by 2 and 10, and the repeated addition (“chunking”) method covered in Multiplication

Short division (bus stop method)

- Unless you can use simple shortcuts such as dividing by 2 or by 10, this method is best used when dividing by a single digit
- To find 174 ÷ 3
  - Starting from the left; 3 fits into 1, 0 times, with a remainder of 1
    - Carry the remainder of 1 over to the next digit, which forms 17
    - $\begin{array}{r} 0 \\ 3\overline{)1\,{}^{1}7\;\;4} \end{array}$

- $3\overline{)1\,{}^{1}7\,{}^{2}4}$ $\;0\;5$

- 3 fits into 24, 8 times, with no remainder
  - $3\overline{)1\,{}^{1}7\,{}^{2}4}$ $\;0\;5\;8$
- So, 174 ÷ 3 = 58

Factorising & cancelling

- This involves treating division as you would if you were asked to simplify fractions
  - For example, 1008 ÷ 28 can be written as $\frac{1008}{28}$
  - This can then be simplified
    - $\frac{1008}{28} = \frac{504}{14} = \frac{252}{7}$
    - 252 ÷ 7 can then be calculated using short division; the answer is 36

Dividing by 10, 100, 1000, … (Powers of 10)

- This is a case of shifting digits along the place value columns
  For example
  - 380 ÷ 10 = 38.0 (shifts by 1 column)
  - 45 ÷ 100 = 0.45 (shifts by 2 columns)
  - 28 ÷ 1000 = 0.028 (shifts by 3 columns)
    - For cases like this, it can help to add leading zeros
    - 0028 ÷ 1000 may be easier to visualise

Worked Example

Divide 568 by 8.

Answer:

This is division by a single digit so short division would be an appropriate method
If you spot it though, 8 is also a power of 2 so you could just halve three times

Using short division, the bus stop method:

8 fits into 5, 0 times, with a remainder of 5
8 fits into 56, 7 times exactly
8 fits into 8, 1 time exactly

Use an estimate to check your answer

- 600 ÷ 10 is equal to 60

Teacher only

Test your students on this in just a few clicks
